

State-transition graph Q_6 : 64 hexagrams, 192 edges, 6-regular

vertices laid out in columns by yang count; a one-line change moves one column left or right

number of yang lines (Hamming weight)

Every edge flips exactly one line, so it always joins the two classes: 0 triangles; bipartite, parts 32 + 32.

clustering coefficient = 0.0 (local) and 0.0 (global) over 960 connected triples
