

Correcting the model changes two of the three information quantities

all values in bits; the cast hexagram carries six bits under either model

$H(M) = 4.8677$ bits for the independent mask, so $I = 6 - H(M) = 1.1323$ bits. Computing I from the actual 2×2 per-line joint instead gives 1.2326 bits: the transformation retains 20.5% of the six bits, not 18.9%.
